Advanced Robotics Lab

Lec02: Sensors, Pose Estimation, Simple Python Projects

James McLurkin
Rice University
jmclurkin@rice.edu

Sensors

Sensors, sensors, everywhere

We're surrounded by sensors

You can sense anything and everything.

For example, let's say you want to sense obstacles:

Lever Switch

IR Range Finder

Sonar

Radar

Lidar

Lidar (smaller)

Lidar (insane)

Map from Sonar

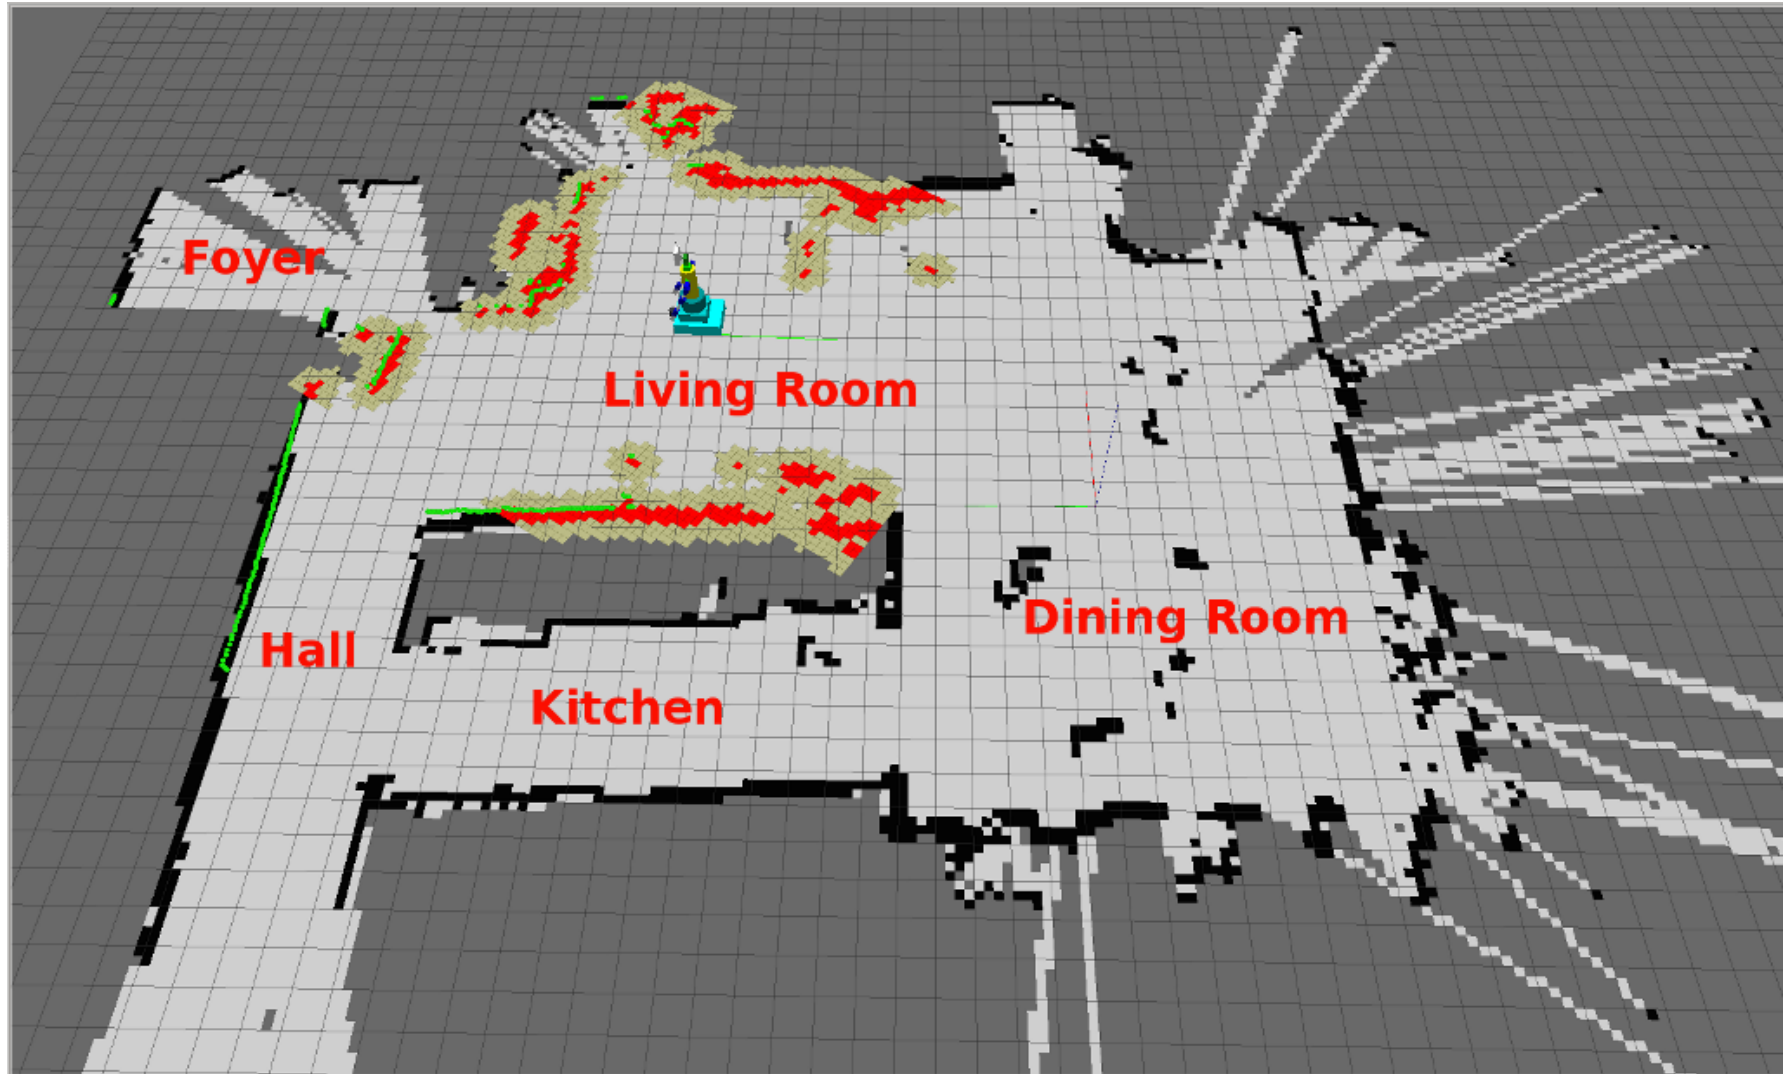

Map from Sonar

Map from Lidar

Map from Lidar

Occupancy Grid Mapping

Use laser scanner to detect obstacles

Use sensor model and “better pose” to produce a map

Particle Filter Localization (MCL)

Produce lots of estimates of current position

Keep the good ones

Particle Filter Localization (MCL)

Produce lots of estimates of current position

Keep the good ones

A grayscale laser range-finder scan of a hallway. The scan shows a central corridor with walls on either side. Overlaid on the scan are numerous red dots representing particle estimates of the robot's position. A large, bold, black text overlay with a red shadow reads "Global localization using a laser range-finder". In the bottom left corner, there is a small blue box containing the number "40000".

**Global localization using
a laser range-finder**

40000

SLAM in Large-Scale Cyclic Environments Using the Atlas Framework

Michael Bosse, Paul Newman,
John Leonard, Seth Teller

International Journal of Robotics Research
February, 2004

The Sensor Model

There are many ways to sense any physical quantity

Each approach has trade-offs in cost, complexity, and accuracy

We need to understand these basic parameters of the ***sensor model*** in order to select the right sensors for the job

We often represent this model as a ***normal distribution...***

Normal Distribution

Looks complex, but can be represented with two parameters

- This is convenient for math
- It can be easily manipulated

Surprisingly accurate

- Even when the underlying physical phenomena is not normal

Using Sensors: Odometry

Pose Estimation

We can describe the robot's *pose* in an external reference frame:
This is useful for getting the robots around in the world

Pose Estimation

We assume the robot starts at $(0, 0, 0)$

We compute incremental changes to the pose using the encoders

This is called *dead reckoning*

Wheel Slippage

Wheels are always slipping, therefore Dead Reckoning is always accruing errors

Even worse, the errors *integrate*, i.e. they increase little by little but have no bound. Soon the robot has **no idea** where it is.

We can do better, right?

Parameters we know

Parameters we want to compute

One Update Step

[The rest is homework]

Using Odometry: Waypoint Navigation

Waypoint Navigation

We assume that we know our current pose

How can we get from one point to another?

We don't want to specify θ_2 , just (x_2, y_2)

Waypoint Navigation

1. Compute θ_{rotate} and d
2. Rotate, then move a fixed distance

No

Small angular errors will be magnified over long d

But we know how to deal with errors: a feedback controller

Waypoint Navigation with a controller

1. While $d > \epsilon$:
 2. Compute θ_{rotate} and d
 3. Rotate while translating

Topic 5:

**The “r-one”
robot**

Sensors and Actuators on the r-one Robot

r-one Robot: Mechanical Design

Absurdly simple (read: elegant) design

- 2 circuit boards
- 3 plastic parts
- 7 off-the-shelf parts
- only 14 screws!

The r-one Sensors and Specifications

McLurkin
[DARS 2010]
