Lecture 05: Braitenberg Vehicles, Finite State Machines, Behavior-Based Programming

James McLurkin Rice University jmclurkin@rice.edu

Braitenberg Vehicles

Braitenberg "Vehicles"

Simplest possible controller

Directly connect sensors to actuators

[refer to pdf file]

Finite-State Machines (Discrete Finite Automata)

Finite-State Machines (Discrete Finite Automata)

Second most simple controller:

Sample FSM diagram:

Q: What does this program do?

Q: Note that the left sensor triggers a right rotate. Does this make sense?

[Review dark avoid code in editor]

Finite-State Machines (Quidditch Version)

Let's say you are programming a "Seeker" robot...

Let's say you are programming a "Seeker" robot ...

Let's say you are programming a "Seeker" robot ...

Let's say you are programming a "Seeker" robot ...

Yikes!

Don't worry, it looks simpler in code...

[switch to PS01.py file]

Behavior-Based Robot Programming

Behavior-Based Control

A behavior is a small program (or finite-state machine) that reads the sensors and controls the robot

- Each behavior only does *one simple* thing
- Each behavior has access to all the sensors of the robot and produces motor outputs (tv, rv, active)

Only one behavior can be active at a time

- There is a *prioritization* of behaviors
- More important ones override, or *subsume*, less important ones

An Example Behavior-Based Program

Follow a robot

- Sensor: IR Communications
- Behavior: Follow another robot

Avoid Obstacles

- Sensors: Bump sensor to detect wall
- Behavior: Move away from wall

Wander

- Sensor: Encoders
- Behavior: Move forward and turn occasionally

Q: Which behavior should have the highest priority?

Q: Which behavior should have the lowest priority?

Combining Behaviors

We combine behaviors by overriding, or *subsuming* lower-priority behaviors if a higher-priority behavior becomes active

lowest priority

Genghis

The behavior-based poster child

Really simple hardware

- 6 legs, 2 motors per leg
 - α -motor for forward/back, β -motor for up/down
- 2 bump sensors (feelers)
- 2 ground detection sensors (switches)
- 6 heat sensors (but they weren't used for walking)

Genghis in Action

Subsumption Architecture

Combining Behaviors

We combine behaviors by overriding, or *subsuming* lower-priority behaviors if a higher-priority behavior becomes active

lowest priority

Great, but how to you program this?

You can abstract this a bit more:

- Write each behavior as a function that returns a tuple of (tv, rv, active)
- write a beh_subsume(high_priority, low_priority) function that returns the high_priority or low_priority output, depending on which has active == True
- If neither behavior is active, it returns the **INACTIVE_BEH** output

```
INACTIVE_BEH = (False, 0.0, 0.0)
wander_out = wander(foo, bar)
gps_out = gps_navigation(bang, zoom)
obstacle_out = obstacle_avoidance(bif, bop)
beh = beh_subsume(gps_out, wander_out)
beh = beh_subsume(obstacle_out, beh)
```

```
velocity.set_tvrv(beh_get_tv(beh), beh_get_rv(beh))
```

Great, but how to you program this?

There are several ways:

- Write each behavior as a function that returns a tuple of (active, tv, rv)
- Write getters to extract the different parts of the tuple
- Use if statements to overwrite the outputs of lower-priority behaviors

```
INACTIVE BEH = (False, 0.0, 0.0)
wander out = wander(foo, bar)
gps navigation out = gps navigation(bang, zoom)
obstacle avoidance out = obstacle avoidance(bif, bop)
beh = INACTIVE BEH
if beh get active(wander out):
    beh = wander out
if beh get active(gps navigation out ):
    beh = \overline{g}ps navigation out
if beh get active (obstacle avoidance out):
    beh = obstacle avoidance out
velocity.set tvrv(beh get tv(beh), beh get rv(beh))
```
